Tangent linear and adjoint models for variational data assimilation

Angela Benedetti

with contributions from:

Marta Janisková, Philippe Lopez, Lars Isaksen, Gabor Radnoti and Yannick Tremolet
**Introduction**

- 4D-Var is based on minimization of a cost function which measures the distance between the model with respect to the observations and with respect to the background state.

- The **cost function and its gradient** are needed in the minimization.

- The tangent linear model provides a computationally efficient (although approximate) way to calculate the model trajectory, and from it the cost function. The adjoint model is a very efficient tool to compute the gradient of the cost function.

- **Overview:**
  - Brief introduction to 4D-Var with focus on TL/AD aspects
  - General definitions of Tangent Linear and Adjoint models and why they are extremely useful in variational assimilation
  - Writing TL and AD models and testing them
  - Brief mention of automatic differentiation software
4D-Var

In 4D-Var the cost function can be expressed as follows:

\[
J = \frac{1}{2} (x_0 - x_b)^T B^{-1}(x_0 - x_b) + \frac{1}{2} \sum_{i=0}^{n} (H_iM_i[x_0] - y_i)^T R_i^{-1} (H_iM_i[x_0] - y_i)
\]

\[J = \begin{cases} \quad J_b \quad & \text{background error covariance matrix}, \\ J_o \quad & \text{observation error covariance matrix (instrumental + interpolation + observation operator error)}, \\ J \quad & \text{forward nonlinear forecast model (time evolution of the model state, index i)}, \\ H \quad & \text{observation operator (model space \rightarrow observation space)}. \end{cases}\]

\[
\min J \iff \nabla_{x_0} J = B^{-1}(x_0 - x_b) + \sum_{i=0}^{n} M_i'^T [t_i, t_0] H_i'^T R_i^{-1} (H_iM_i[x_0] - y_i) = 0
\]

\[H'^T = \text{adjoint of observation operator and } M'^T = \text{adjoint of forecast model}.\]
Incremental 4D-Var at ECMWF

• In incremental 4D-Var, the cost function is minimized in terms of increments:

\[ \delta x_i = M'[t_0, t_i] \delta x_0 \]

with the model state defined at any time \( t_i \) as: \( x_i = x_{ti} + \delta x_i, x_{ti} = M(t_0, t_i)x_{i0} \)

\( x_t \) is the trajectory around which the linearization is performed (\( x_t = x_b \) at \( t=0 \))

• 4D-Var cost function can then be approximated to the first order by:

\[ J(\delta x_0) = \frac{1}{2} \delta x_0^T B^{-1} \delta x_0 + \frac{1}{2} \sum_{i=0}^{n} (H_i' M'[t_0, t_i] \delta x_0 - d_i)^T R^{-1} (H_i' M'[t_0, t_i] \delta x_0 - d_i) \]

where \( d_i = y_i - H_i(x_{ti}) \) is the so-called departure computed using the nonlinear model and observational operator.

• The gradient of the cost function to be minimized is:

\[ \min J \iff \nabla_{\delta x_0} J = B^{-1} \delta x_0 + \sum_{i=0}^{n} M'^T[t_i, t_0] H_i'^T R^{-1} \left( H_i' \delta x_i - d_i \right) = 0 \]

\( M' \) and \( H_i' \) are the tangent linear models which are used in the computations of incremental updates during the minimization (iterative procedure).

\( M'^T \) and \( H_i'^T \) are the adjoint models which are used to obtain the gradient of the cost function with respect to the initial condition.
Details on linearisation

In the first order approximation, a perturbation $\delta x$ of the control variable (initial condition) evolves according to the tangent linear model:

$$
\delta x_i = \left[ \frac{\partial M_i(x)}{\partial x} \right]_{x_{i-1}} \\
\delta x_{i-1} = M_i' \delta x_{i-1}
$$

where $i$ is the time-step index.

The perturbation of the cost function around the initial state is:

$$
\delta J(x_0, \delta x_0) = \frac{1}{2} \delta x_0^T B^{-1} \delta x_0 + \frac{1}{2} \sum_{i=0}^{n} \left( H_i' \delta x_i - d_i \right)^T R_i^{-1} \left( H_i' \delta x_i - d_i \right) =
$$

$$
= \frac{1}{2} \delta x_0^T B^{-1} \delta x_0 + \frac{1}{2} \sum_{i=0}^{n} \left( H_i' M_i' M_{i-1}' ...... M_0' \delta x_0 - d_i \right)^T R_i^{-1} \left( H_i' M_i' M_{i-1}' ...... M_0' \delta x_0 - d_i \right)
$$

where $H_i'$ is the linearised version of $H_i$ about $x_i$ and $d_i = y_i - H_i(x_i)$ are the departures from observations.
The gradient of the cost function with respect to $\delta x_0$ is given by:

$$\nabla_{\delta x_0} J = B^{-1} \delta x_0 + \sum_{i=0}^{n} (H_i'M_i'M_{i-1}'...M_0')^T R^{-1} (H_i'M_i'M_{i-1}'...M_0' \delta x_0 - d_i) =$$

remembering that $(AB)^T = B^T A^T$

$$= B^{-1} \delta x_0 + \sum_{i=0}^{n} M_0'^T ... M_{i-1}'T M_i'^T H_i'^T R^{-1} (H_i'M_i'M_{i-1}'...M_0' \delta x_0 - d_i) =$$

$$= B^{-1} \delta x_0 + \sum_{i=0}^{n} M_i'^T [t_i, t_0] H_i'^T R^{-1} (H_i' \delta x_i - d_i)$$

The optimal initial perturbation is obtained by finding the value of $\delta x_0$ for which:

$$\nabla_{\delta x_0} J = 0$$

The gradient of the cost function with respect to the initial condition is provided by the adjoint solution at time t=0. Let’s see how…
Definition of adjoint operator

For any linear operator $M'$ there exist an adjoint operator $M^*$ such as:

$$\langle x, M' y \rangle = \langle M^* x, y \rangle$$

where $\langle , \rangle$ is an inner scalar product and $x$, $y$ are vectors (or functions) of the space where this product is defined.

It can be shown that for the inner product defined in the Euclidean space:

$$M^* = M'^T$$

We will now show that the gradient of the cost function at time $t=0$ is provided by the solution of the adjoint equations at the same time:

$$\nabla_{\delta x_0} J = -x_0^*$$
Adjoint solution

Usually the initial guess \( x_0 \) is chosen to be equal to the background \( x_b \) so that the initial perturbation \( \delta x_0 = 0 \). The gradient of the cost function is hence simplified as:

\[
\nabla_{\delta x_0} J = - \sum_{i=0}^{n} M'^T [t_i, t_0] H_i'^T R^{-1} d_i
\]

We choose the solution of the adjoint system as follows:

\[
\begin{align*}
x^*_{n+1} &= 0 \quad \text{(arbitrary “final” condition)} \\
x^*_0 &= M_1 x_1^* \quad \text{(initial condition)} \\
x_i^* &= M^*_1 x_{i+1}^* + H_i'^* R^{-1} d_i, i = 1, \ldots, n \quad \text{(iterative solution)}
\end{align*}
\]

We then substitute progressively the solution \( x_i^* \) into the expression for \( x_0^* \).
Adjoint solution (cnt.)

\[ x_0^* = M_1^* (M_2^* x_2^*) + M_1^* H_1^* R^{-1} d_1 = \]
\[ = M_1^* (M_2^* (M_3^* x_3^*)) + M_1^* M_2^* H_2^* R^{-1} d_2 + M_1^* H_1^* R^{-1} d_1 = \]
\[ = \ldots \]

Finally, regrouping and remembering that \( x_{n+1}^* = 0 \) and that \( M^* = M'^T \) and \( H^* = H'^T \) we obtain the following equality:

\[ x_0^* = \sum_{i=0}^{n} M'^T [t_i, t_0] H'^T R^{-1} d_i \quad \Rightarrow x_0^* = -\nabla_{\delta x_0} J \]

The gradient of the cost function with respect to the control variable (initial condition) is obtained by a backward integration of the adjoint model.
Iterative steps in the 4D-Var Algorithm

1. Integrate forward model gives $J$.
2. Integrate adjoint model backwards gives $\nabla J$.
3. If $\|\nabla J(x_m)\| \leq \varepsilon$ then stop.
4. Compute descent direction $D_m$ (Newton, CG, …).
5. Compute step size $\rho_m$: $J(x_m + \rho_m D_m) = \min_{\rho} J(x_m + \rho D_m)$.
6. Update initial condition: $x_{m+1} = x_m + \rho_m D_m$. 
Finding the minimum of cost function $J$ is an iterative minimization procedure.

$$x_{m+1} = x_m + \rho_m D_m$$
An analysis cycle in 4D-Var

1st ifstraj:
- Non-linear model is used to compute the high-res trajectory (T1279 operational, 12-h forecast)
- High-res departures are computed at exact obs time and location
- Trajectory is interpolated at low res (T159)

1st ifsmin (70 iterations):
- Iterative minimization at T159 resolution
- Tangent linear with simplified physics to calculate the increments $\delta x_j$
- The Adjoint is used to compute the gradient of the cost function with respect to the departure in initial condition $\nabla J_{\delta x_0}$
- Analysis increment at initial time $\delta x_0$ is interpolated back linearly from low-res to high-res and it provides a new initial state for the 2nd trajectory run

2nd ifstraj:
- repeat 1st ifstraj and interpolates at T255 resolution

2nd ifsmin (30 iterations):
- repeat 1st ifsmin at T255

Last ifstraj:
- Uses updated initial condition to run another 12-h forecast and stores analysis departures in the Observational Data Base (ODB)
Recap on TL and AD models

- **TANGENT LINEAR MODEL**
  
  If \( M \) is a model such as:
  \[
  x(t_{i+1}) = M[x(t_i)]
  \]

  then the tangent linear model of \( M \), called \( M' \), is:
  \[
  \delta x(t_{i+1}) = M'[x(t_i)]\delta x(t_i) = \frac{\partial M[x(t_i)]}{\partial x} \delta x(t_i)
  \]

- **ADJOINT MODEL**
  
  The adjoint of a linear operator \( M' \) is the linear operator \( M^* \) such that, for the inner product \( <,> \),
  \[
  \forall x, \forall y \quad < M'x, y > = < x, M^*y >
  \]

  Remarks:
  - with the euclidian inner product, \( M^* = M'^T \).
  - in variational assimilation, \( \nabla_x \mathcal{J} = M^* \nabla_y \mathcal{J} \), where \( \mathcal{J} \) is the cost function.
Simple example of adjoint writing

- **non-linear statement**

\[
\begin{align*}
x & = y + z^2 \\
z & = z \\
y & = y \\
x & = y + z^2
\end{align*}
\]

- **tangent linear statement**

\[
\begin{align*}
\delta z & = \delta z \\
\delta y & = \delta y \\
\delta x & = \delta y + 2z\delta z
\end{align*}
\]

or in a matrix form:

\[
\begin{pmatrix}
\delta z \\ \\
\delta y \\ \\
\delta x
\end{pmatrix} =
\begin{pmatrix}
1 & 0 & 0 \\ \\
0 & 1 & 0 \\ \\
2z & 1 & 0
\end{pmatrix}
\begin{pmatrix}
\delta z \\ \\
\delta y \\ \\
\delta x
\end{pmatrix}
\]
Simple example of adjoint writing (cnt.)

Often the adjoint variables in mathematical formulations are indicated with an asterisk

- **adjoint statement**
  - transpose matrix

\[
\begin{pmatrix}
\delta z^* \\
\delta y^* \\
\delta x^*
\end{pmatrix}
=
\begin{pmatrix}
1 & 0 & 2z \\
0 & 1 & 1 \\
0 & 0 & 0
\end{pmatrix}
\cdot
\begin{pmatrix}
\delta z^* \\
\delta y^* \\
\delta x^*
\end{pmatrix}
\]

or in the form of equation set:

\[
\begin{align*}
\delta z^* &= \delta z^* + 2z\delta x^* \\
\delta y^* &= \delta y^* + \delta x^* \\
\delta x^* &= 0
\end{align*}
\]

Do not forget the last equation!!! That too is part of the adjoint!

As an alternative to the matrix method, adjoint coding can be carried out using a **line-by-line** approach.
More practical examples on adjoint coding: the Lorenz model

\[ \frac{dx_1}{dt} = -px_1 + px_2 \]  \hspace{1cm} (1)
\[ \frac{dx_2}{dt} = (r - x_3)x_1 - x_2 \]  \hspace{1cm} (2)
\[ \frac{dx_3}{dt} = x_1x_2 - bx_3 \]  \hspace{1cm} (3)

where \( p \) is the Prandtl number, \( r \) the Rayleigh number, and \( b \) the aspect ratio.

\( x_1 \) is the intensity of convection,
\( x_2 \) is the maximum temperature difference
\( x_3 \) is the stratification change due to convection.

Details on the Lorenz model can be found in the references.
The linear code in Fortran

Linearize each line of the code one by one, and set $dx/dt=y$ for simplicity:

\[
\begin{align*}
y(1) & = -p \times x(1) + p \times x(2) & \text{: Nonlinear statement} \\
yd(1) & = -p \times xd(1) + p \times xd(2) & \text{: Tangent linear}
\end{align*}
\]

\[
\begin{align*}
y(2) & = x(1) \times (r - x(3)) - x(2) & \text{: Nonlinear statement} \\
yd(2) & = xd(1) \times (r - x(3)) \\
& \quad - x(1) \times xd(3) - xd(2) & \text{: Tangent linear}
\end{align*}
\]

...etc

Remember that $p$, $r$, $b$ are constants; $x(1)$, $x(2)$ and $x(3)$ are the independent variables; $y(1)$, $y(2)$ and $y(3)$ are the dependent variables.

We chose the suffix “d” for the tangent linear variable for consistency with the automatic differentiation software TAPENADE (see optional practical exercise). Adjoint variables are indicated with the suffix “b”. This is just a convention.

Note that in the ECMWF Integrated Forecast System (IFS) the tangent linear and adjoint variables are indicated without any subscripts and the nonlinear trajectory ($x$) is indicated with the suffix “5” ($x5$).
Adjoint of one instruction

We start from the tangent linear code:

\[ y_d(1) = -p * x_d(1) + p * x_d(2) \]

In matrix form, it can be written as:

\[
\begin{pmatrix}
\delta x_1 \\
\delta x_2 \\
\delta y_1
\end{pmatrix} =
\begin{pmatrix}
1 & 0 & 0 \\
0 & 1 & 0 \\
-p & p & 0
\end{pmatrix}
\begin{pmatrix}
\delta x_1 \\
\delta x_2 \\
\delta y_1
\end{pmatrix}
\]

which can easily be transposed (asterisk indicates adjoint variables):

\[
\begin{pmatrix}
\delta x_1^* \\
\delta x_2^* \\
\delta y_1^*
\end{pmatrix} =
\begin{pmatrix}
1 & 0 & -p \\
0 & 1 & p \\
0 & 0 & 0
\end{pmatrix}
\begin{pmatrix}
\delta x_1^* \\
\delta x_2^* \\
\delta y_1^*
\end{pmatrix}
\]

The corresponding adjoint code in FORTRAN is:

\[
\begin{align*}
x_b(1) &= x_b(1) - p * y_b(1) \\
x_b(2) &= x_b(2) + p * y_b(1) \\
y_b(1) &= 0
\end{align*}
\]
Adjoint of one instruction (II)

We start again from the tangent linear code:

\[ y_d(2) = x_d(1) \cdot (r - x(3)) - x_d(2) - x(1) \cdot x_d(3) \]

In matrix form, it can be written as:

\[
\begin{pmatrix}
\delta x_1 \\
\delta x_2 \\
\delta x_3 \\
\delta y_2
\end{pmatrix}
= \begin{pmatrix}
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
(r - x_3) & -1 & -x_1 & 0
\end{pmatrix}
\begin{pmatrix}
\delta x_1 \\
\delta x_2 \\
\delta x_3 \\
\delta y_2
\end{pmatrix}
\]

which can easily be transposed (asterisk indicates transposition):

\[
\begin{pmatrix}
\delta x_1^* \\
\delta x_2^* \\
\delta x_3^* \\
\delta y_2^*
\end{pmatrix}
= \begin{pmatrix}
1 & 0 & 0 & (r - x_3) \\
0 & 1 & 0 & -1 \\
0 & 0 & 1 & -x_1 \\
0 & 0 & 0 & 0
\end{pmatrix}
\begin{pmatrix}
\delta x_1^* \\
\delta x_2^* \\
\delta x_3^* \\
\delta y_2^*
\end{pmatrix}
\]

The corresponding adjoint code in FORTRAN is:

\[
\begin{align*}
x_b(1) &= x_b(1) + (r - x(3)) \cdot y_b(2) \\
x_b(2) &= x_b(2) - y_b(2) \\
x_b(3) &= x_b(3) - x(1) \cdot y_b(2) \\
y_b(2) &= 0
\end{align*}
\]
The trajectory has to be available. It can be:

- saved which costs memory,
- recomputed which costs CPU time.

Depending on the complexity of the code, one option or the other is adopted (or both options at the same time).
The Adjoint Code

Property of adjoints (transposition):

\[(L_n L_{n-1} \ldots L_2 L_1)^* = L_1^* L_2^* \ldots L_{n-1}^* L_n^*)\]

Application: \[M_i = L_n L_{n-1} \ldots L_2 L_1\] where \[L_i\] represents the line \(i\) of the tangent linear model.

The **adjoint code** is made of the **transpose** of each line of the tangent linear code in **reverse order**.
Adjoint of loops

In the TL code for the Lorenz model we have:

\[
\begin{align*}
\text{DO } &i=1,3 \\
& \quad x_d(i) = x_d(i) + dt \cdot y_d(i) \\
\text{ENDDO}
\end{align*}
\]

\(dt\) is a constant for our purposes. This loop can be written explicitly:

\[
\begin{align*}
x_d(1) &= x_d(1) + dt \cdot y_d(1) \\
x_d(2) &= x_d(2) + dt \cdot y_d(2) \\
x_d(3) &= x_d(3) + dt \cdot y_d(3)
\end{align*}
\]

We can now transpose and reverse the lines to get the adjoint:

\[
\begin{align*}
y_b(3) &= y_b(3) + dt \cdot x_b(3) \\
y_b(2) &= y_b(2) + dt \cdot x_b(2) \\
y_b(1) &= y_b(1) + dt \cdot x_b(1)
\end{align*}
\]

which is equivalent to

\[
\begin{align*}
\text{DO } &i=3,1,-1 \quad !\text{Reverse order of indeces!} \\
& \quad y_b(i) = y_b(i) + dt \cdot x_b(i) \\
\text{ENDDO}
\end{align*}
\]
Conditional statements ("IF" statements)

• What we want is the adjoint of the statements which were actually executed in the direct model.

• We need to know which "branch" of the IF statement was executed

• The result of the conditional statement has to be stored: it is part of the trajectory !!!
Summary of basic rules for line-by-line adjoint coding (1)

Adjoint statements are derived from tangent linear ones in a reversed order

<table>
<thead>

</table>
| $\delta x = A \delta y + B \delta z$ | $\delta y^* = \delta y^* + A \delta x^*$  
|                      | $\delta z^* = \delta z^* + B \delta x^*$ |
| $\delta x = A \delta x + B \delta z$ | $\delta x^* = A \delta x^*$ |
| do k = 1, N          | do k = N, 1, −1 (Reverse the loop!) |
| $\delta x(k) = A \delta x(k−1) + B \delta y(k)$ | $\delta x^*(k−1) = \delta x^*(k−1) + A \delta x^*(k)$  
| end do               | $\delta y^*(k) = \delta y^*(k) + B \delta x^*(k)$ |
|                      | $\delta x^*(k) = 0$ |

Order of operations is important when variable is updated!

And do not forget to initialize local adjoint variables to zero!
### Summary of basic rules for line-by-line adjoint coding (2)

To save memory, the trajectory can be recomputed just before the adjoint calculations (again it depends on the complexity of the model).

</tbody>
</table>

The most common sources of error in adjoint coding are:

1) Pure coding errors
2) Forgotten initialization of local adjoint variables to zero
3) Mismatching trajectories in tangent linear and adjoint (even slightly)
4) Bad identification of trajectory updates
More facts about adjoints

• The adjoint always exists and it is unique, assuming spaces of finite dimension. Hence, coding the adjoint does not raise questions about its existence, only questions related to the technical implementation.

• In the meteorological literature, the term *adjoint* is often improperly used to denote the adjoint of the tangent linear of a non-linear operator. In reality, the adjoint can be defined for any linear operator. One must be aware that discussions about the existence of the *adjoint* usually should address the existence of the tangent linear model.

• Without re-computation, the cost of the TL is usually about 1.5 times that of the non-linear code, the cost of the adjoint between 2 and 3 times.

• The tangent linear model is not strictly necessary to run a 4D-Var system (but it is needed in the incremental 4D-Var formulation in use operationally at ECMWF). It is also needed as an intermediate step to write and test the adjoint.
Test for tangent linear model

- Taylor formula:

\[
\lim_{\lambda \to 0} \frac{M(x + \lambda \delta x) - M(x)}{M'(\lambda \delta x)} = 1

\{ machine precision reached \}
Test for adjoint model

- **adjoint identity:**

\[ \forall x, \forall y \quad < M'.x, y > = < x, M*.y > \]

\[
< F(X), Y > = -0.13765102625251640000E-01 \\
< X, F^*(Y) > = -0.13765102625251680000E-01 \\
\text{ratio of norms} = 1.0000000000000005 \\
\text{THE DIFFERENCE IS 11.351 TIMES THE ZERO OF THE MACHINE}
\]

The adjoint test is truly unforgiving. If you do not have a ratio of the norm close to 1 within the precision of the machine, you know there is a bug in your adjoint. At the end of your debugging you will have a **perfect** adjoint. If properly tested, the adjoint is the only piece of code on Earth to be entirely bug-free (although you may still have an imperfect tangent linear)!
Test of adjoint in practice...

- Compute perturbed variable (y) using perturbation in input variables (x,z) with the tangent linear code
  \[
  \delta y = \frac{\partial y}{\partial x} \delta x + \frac{\partial y}{\partial z} \delta z
  \]

- Compute TL norm:
  \[
  NORM\_TL = \|\delta y\|^2
  \]

- Call adjoint routine to obtain gradients in x and z with respect to initial perturbation in x and z \((\delta x_0, \delta z_0)\) from perturbation in y.
  \[
  \delta x^* = \delta x^* + \left(\frac{\partial y}{\partial x}\right) \delta x^*
  \]
  \[
  \delta z^* = \delta z^* + \left(\frac{\partial y}{\partial z}\right) \delta z^*
  \]

- Compute the norm from the adjoint calculation, using unperturbed state and gradients:
  \[
  NORM\_AD = \delta x_0 \delta x^* + \delta z_0 \delta z^*
  \]

- According to the test of adjoint \(NORM\_TL\) must be equal to \(NORM\_AD\) to the machine precision!
Automatic differentiation

• Because of the strict rules of tangent linear and adjoint coding, automatic differentiation is possible.

• Existing tools: TAF (TAMC), TAPENADE (Odyssée), ...
  – Reverse the order of instructions,
  – Transpose instructions instantly without typos !!!
  – Especially good in deriving tangent linear codes!

• There are still unresolved issues:
  – It is **NOT** a black box tool,
  – Cannot handle non-differentiable instructions (TL is wrong),
  – Can create huge arrays to store the trajectory,
  – The codes often need to be cleaned-up and optimised.

• Look in the “Supplementary material” for more information!
